## 1 Introduction

Given the opportunity to review the design document and related source code of the ZKT smart contracts, we outline in the report our systematic approach to evaluate potential security issues in the smart contract implementation, expose possible semantic inconsistencies between smart contract code and design document, and provide additional suggestions or recommendations for improvement. Our results show that the given version of smart contracts can be further improved due to the presence of several issues related to either security or performance. This document outlines our audit results.

#### 1.1 About ZKT

As the native token of the zkTube protocol, ZKT represents the rights of the holder and also has other practical uses. The usage scenarios of ZKT include certificate of community participation in governance, transaction fee and fuel in the zkTube network, mining, cryptocurrency assets, and circulation in DeFi and NFT.

The basic information of audited contracts is as follows:

Item Description

Name zkTube

Website https://zktube.io/

Type Ethereum Smart Contract

Platform Solidity

Audit Method Whitebox

Latest Audit Report August 12, 2021

Table 1.1: Basic Information of ZKT

In the following, we show the MD5 hash value of the related compressed file with the contracts for audit:

MD5 (ZKTContracts audit.zip) = 26a3b924a12783f0f8f9bc2043b3fa88

#### 1.2 About PeckShield

PeckShield Inc. [9] is a leading blockchain security company with the goal of elevating the security, privacy, and usability of current blockchain ecosystems by offering top-notch, industry-leading services and products (including the service of smart contract auditing). We are reachable at Telegram (https://t.me/peckshield), Twitter (http://twitter.com/peckshield), or Email (contact@peckshield.com).

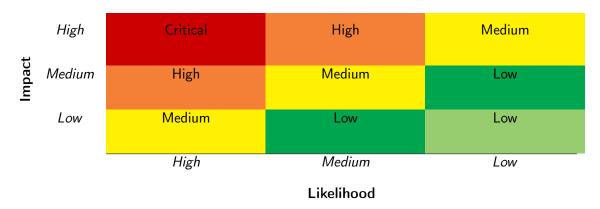

Table 1.2: Vulnerability Severity Classification

### 1.3 Methodology

To standardize the evaluation, we define the following terminology based on OWASP Risk Rating Methodology [8]:

- <u>Likelihood</u> represents how likely a particular vulnerability is to be uncovered and exploited in the wild:
- Impact measures the technical loss and business damage of a successful attack;
- Severity demonstrates the overall criticality of the risk.

Likelihood and impact are categorized into three ratings: *H*, *M* and *L*, i.e., *high*, *medium* and *low* respectively. Severity is determined by likelihood and impact, and can be accordingly classified into four categories, i.e., *Critical*, *High*, *Medium*, *Low* shown in Table 1.2.

To evaluate the risk, we go through a list of check items and each would be labeled with a severity category. For one check item, if our tool or analysis does not identify any issue, the contract is considered safe regarding the check item. For any discovered issue, we might further deploy contracts on our private testnet and run tests to confirm the findings. If necessary, we would

	Making Type Inference Explicit		
	Adhering To Function Declaration Strictly		
	Following Other Best Practices		

additionally build a PoC to demonstrate the possibility of exploitation. The concrete list of check items is shown in Table 1.3.

In particular, we perform the audit according to the following procedure:

- Basic Coding Bugs: We first statically analyze given smart contracts with our proprietary static code analyzer for known coding bugs, and then manually verify (reject or confirm) all the issues found by our tool.
- <u>Semantic Consistency Checks</u>: We then manually check the logic of implemented smart contracts and compare with the description in the white paper.
- Advanced DeFi Scrutiny: We further review business logics, examine system operations, and place DeFi-related aspects under scrutiny to uncover possible pitfalls and/or bugs.
- Additional Recommendations: We also provide additional suggestions regarding the coding and development of smart contracts from the perspective of proven programming practices.

To better describe each issue we identified, we categorize the findings with Common Weakness Enumeration (CWE-699) [7], which is a community-developed list of software weakness types to better delineate and organize weaknesses around concepts frequently encountered in software development. Though some categories used in CWE-699 may not be relevant in smart contracts, we use the CWE categories in Table 1.4 to classify our findings. Moreover, in case there is an issue that may affect an active protocol that has been deployed, the public version of this report may omit such issue, but will be amended with full details right after the affected protocol is upgraded with respective fixes.

#### 1.4 Disclaimer

Note that this security audit is not designed to replace functional tests required before any software release, and does not give any warranties on finding all possible security issues of the given smart contract(s) or blockchain software, i.e., the evaluation result does not guarantee the nonexistence of any further findings of security issues. As one audit-based assessment cannot be considered comprehensive, we always recommend proceeding with several independent audits and a public bug bounty program to ensure the security of smart contract(s). Last but not least, this security audit should not be used as investment advice.

Table 1.4: Common Weakness Enumeration (CWE) Classifications Used in This Audit

Category	Summary		
Configuration	Weaknesses in this category are typically introduced during		
	the configuration of the software.		
Data Processing Issues	Weaknesses in this category are typically found in functional-		
	ity that processes data.		
Numeric Errors	Weaknesses in this category are related to improper calcula-		
	tion or conversion of numbers.		
Security Features	Weaknesses in this category are concerned with topics like		
	authentication, access control, confidentiality, cryptography,		
	and privilege management. (Software security is not security		
	software.)		
Time and State	Weaknesses in this category are related to the improper man-		
	agement of time and state in an environment that supports		
	simultaneous or near-simultaneous computation by multiple		
Forman Canadiai ana	systems, processes, or threads.		
Error Conditions,	Weaknesses in this category include weaknesses that occur if		
Return Values, Status Codes	a function does not generate the correct return/status code, or if the application does not handle all possible return/status		
Status Codes	codes that could be generated by a function.		
Resource Management	Weaknesses in this category are related to improper manage		
Nesource Management	ment of system resources.		
Behavioral Issues	Weaknesses in this category are related to unexpected behav-		
Deliavioral issues	iors from code that an application uses.		
Business Logics	Weaknesses in this category identify some of the underlying		
Dusiness Togics	problems that commonly allow attackers to manipulate the		
	business logic of an application. Errors in business logic can		
	be devastating to an entire application.		
Initialization and Cleanup	Weaknesses in this category occur in behaviors that are used		
	for initialization and breakdown.		
Arguments and Parameters	Weaknesses in this category are related to improper use of		
	arguments or parameters within function calls.		
Expression Issues	Weaknesses in this category are related to incorrectly written		
	expressions within code.		
Coding Practices	Weaknesses in this category are related to coding practices		
	that are deemed unsafe and increase the chances that an ex-		
	ploitable vulnerability will be present in the application. They		
	may not directly introduce a vulnerability, but indicate the		
	product has not been carefully developed or maintained.		

# 2 Findings

#### 2.1 Summary

Here is a summary of our findings after analyzing the design and implementation of the ZKT smart contracts. During the first phase of our audit, we study the smart contract source code and run our in-house static code analyzer through the codebase. The purpose here is to statically identify known coding bugs, and then manually verify (reject or confirm) issues reported by our tool. We further manually review business logics, examine system operations, and place DeFi-related aspects under scrutiny to uncover possible pitfalls and/or bugs.

Severity	# of Findings		
Critical	0		
High	0		
Medium	1		
Low	1		
Informational	1		
Total	3		

We have so far identified a list of potential issues: some of them involve subtle corner cases that might not be previously thought of, while others refer to unusual interactions among multiple contracts. For each uncovered issue, we have therefore developed test cases for reasoning, reproduction, and/or verification. After further analysis and internal discussion, we determined a few issues of varying severities need to be brought up and paid more attention to, which are categorized in the above table. More information can be found in the next subsection, and the detailed discussions of each of them are in Section 3.

### 2.2 Key Findings

Overall, these smart contracts are well-designed and engineered, though the implementation can be improved by resolving the identified issues (shown in Table 2.1), including 1 medium-severity vulnerability, 1 low-severity vulnerability, and 1 informational recommendation.

Table 2.1: Key Audit Findings

ID	Severity	Title	Category	Status
PVE-001	Low	Improved Sanity Checks For System Pa-	Coding Practices	Confirmed
		rameters		
PVE-002	Informational	Incompatibility with Deflationary/Re-	Business Logic	Confirmed
		basing Tokens		
PVE-003	Medium	Trust Issue of Admin Keys	Security Features	Confirmed

Beside the identified issues, we emphasize that for any user-facing applications and services, it is always important to develop necessary risk-control mechanisms and make contingency plans, which may need to be exercised before the mainnet deployment. The risk-control mechanisms should kick in at the very moment when the contracts are being deployed on mainnet. Please refer to Section 3 for details.

## 3 Detailed Results

#### 3.1 Improved Sanity Checks For System Parameters

• ID: PVE-001

Severity: Low

Likelihood: Low

• Impact: Low

• Target: ZKTDeposit

• Category: Coding Practices [5]

• CWE subcategory: CWE-1126 [1]

#### Description

DeFi protocols typically have a number of system-wide parameters that can be dynamically configured on demand. The ZKT protocol is no exception. Specifically, if we examine the ZKTDeposit contract, it has defined a system-wide risk parameter: lockTime. In the following, we show the corresponding routine that allows for its changes.

```
function updateLockTime(uint lockTime_) external onlyOwner {
    lockTime = lockTime_;
    emit UpdateLockTime(msg.sender, lockTime_);
}
```

Listing 3.1: ZKTDeposit::updateLockTime()

This parameter defines the lock time when <code>zkTube</code> users deposit their <code>ZKT</code> tokens into the <code>ZKTDeposit</code> contract and need to exercise extra care when configuring or updating it. Our analysis shows the update logic on this parameter can be improved by applying more rigorous sanity check. Based on the current implementation, certain corner cases may lead to an undesirable consequence. For example, an unlikely mis-configuration of <code>lockTime</code> may set a huge lock time, resulting in the <code>zkTube</code> users' assets permanently locked in the <code>ZKTDeposit</code> contract.

**Recommendation** Validate any change regarding this system-wide parameter to ensure it fall in an appropriate range.

Status The issue has been confirmed. The zkTube team decides to leave it as the lockTime

can only be set by the administrator. Unless there is a practical need in business, it will not be set repeatedly, nor will it be set to a large value.

### 3.2 Incompatibility with Deflationary/Rebasing Tokens

• ID: PVE-002

• Severity: Informational

• Likelihood: N/A

Impact: N/A

• Target: ZKTWhiteList

• Category: Business Logic [6]

• CWE subcategory: CWE-841 [3]

#### Description

In ZKT, the ZKTWhiteList contract is designed for zkTube users to change their ZKTR tokens to ZKT tokens. In particular, one entry routine, i.e., deposit(), accepts user deposits of supported assets (e.g., ZKTR). Naturally, the contract implements a number of low-level helper routines to transfer assets in or out of the pool. These asset-transferring routines work as expected with standard ERC20 tokens: namely the vault's internal asset balances are always consistent with actual token balances maintained in individual ERC20 token contract. In the following, we show the deposit() routine that is used to deposit ZKTR tokens to the ZKTWhiteList contract.

```
function deposit(uint amount) external whenNotPaused lock {
57
58
            require(amount > 0, "ZKTWhiteList: amount is zero");
59
            zktrToken.safeTransferFrom(msg.sender, address(this), amount);
60
            _addDeposit(msg.sender, amount);
61
            deposits[msg.sender] = deposits[msg.sender] + amount;
62
            totalDeposits = totalDeposits + amount;
63
            emit Deposit(msg.sender, amount);
64
65
66
        function withdraw(uint amount) external lock {
67
            require(amount > 0, "ZKTWhiteList: amount is zero");
68
            require(amount <= _available(msg.sender, getCurrentTime() / ONE_DAY), "</pre>
                ZKTWhiteList: available is not enough");
69
            // update
70
            _addReleased(msg.sender, amount);
71
            withdrawals[msg.sender] = withdrawals[msg.sender] + amount;
72
            totalWithdrawals = totalWithdrawals + amount;
73
74
            zktToken.safeTransfer(msg.sender, amount);
75
            emit Withdraw(msg.sender, amount);
76
```

Listing 3.2: ZKTWhiteList::deposit()/withdraw()

However, there exist other ERC20 tokens that may make certain customizations to their ERC20 contracts. One type of these tokens is deflationary tokens that charge a certain fee for every transfer () or transferFrom(). (Another type is rebasing tokens such as YAM.) As a result, this may not meet the assumption behind these low-level asset-transferring routines. In other words, the above operations, such as deposit(), may introduce unexpected balance inconsistencies when comparing internal asset records with external ERC20 token contracts.

One possible mitigation is to measure the asset change right before and after the asset-transferring routines. In other words, instead of expecting the amount parameter in transferFrom() will always result in full transfer, we need to ensure the increased or decreased amount in the ZKTWhiteList contract before and after the transferFrom() is expected and aligned well with our operation. Though these additional checks cost additional gas usage, we consider they are necessary to deal with deflationary tokens or other customized ones if their support is deemed necessary.

We emphasize that the current implementation of <code>ZKTWhiteList</code> is safe as it accepts none-deflationary tokens, i.e., <code>ZKTR</code> for deposits. However, the current code implementation is generic in supporting various tokens and there is a need to highlight the possible pitfall from the audit perspective.

Recommendation If current codebase needs to support possible deflationary tokens, it is better to check the balance before and after the safeTransferFrom() call to ensure the book-keeping amount is accurate. This support may bring additional gas cost. Also, keep in mind that certain tokens may not be deflationary for the time being. However, they could have a control switch that can be exercised to turn them into deflationary tokens. One example is the widely-adopted USDT.

**Status** This issue has been confirmed. The zkTube team confirmed that ZKT token is not of deflationary type and the related contracts source code will be available on mainnet.

### 3.3 Trust Issue of Admin Keys

• ID: PVE-003

Severity: MediumLikelihood: Medium

• Impact: Medium

• Target: Multiple contracts

• Category: Security Features [4]

• CWE subcategory: CWE-287 [2]

#### Description

In the ZKT contracts, there are two special administrative accounts, i.e., \_owner and admin. These two privileged accounts play critical roles in governing and regulating the entire operation and mainte-

nance. We examine closely the ZKT contracts and identify below trust issues on these two privileged accounts.

Firstly, we note that the pause() and unpause() functions allow for the \_owner to set the ZKTWhiteList contract state to be paused or unpaused. The zkTube users can only deposit their ZKTR tokens when ZKTWhiteList contract is in unpaused state.

```
82  function pause() public onlyOwner {
83    __pause();
84  }
85  
86  function unpause() public onlyOwner {
87    __unpause();
88  }
```

Listing 3.3: ZKTWhiteList::pause()/unpause()

Secondly, we note that the updateLockedPosition() function of ZKTVesting contract allows for the \_owner to update the lockedPosition. This state variable determines the number of ZKT token rewards that the zkTube users can claim every day.

```
function updateLockedPosition(uint lockedPosition_) external onlyOwner {
    require(lockedPosition_ <= 100, "ZKTVesting: lockedPosition too big");
    lockedPosition = lockedPosition_;
    emit UpdateLockedPosition(msg.sender, lockedPosition_);
}</pre>
```

Listing 3.4: ZKTVesting::updateLockedPosition()

Thirdly, we note that the updateLockTime() function of ZKTDeposit contract allows for the \_owner to update the lockTime. This state variable determines how long the users' ZKT token will be locked in the ZKTDeposit contract.

```
function updateLockTime(uint lockTime_) external onlyOwner {
    lockTime = lockTime_;
    emit UpdateLockTime(msg.sender, lockTime_);
}
```

Listing 3.5: ZKTDeposit::updateLockTime()

Lastly, we note that the admin account has the power to update the logic implementations for contracts ZKTWhiteList, ZKTVesting, and ZKTDeposit.

Listing 3.6: ZKTWhiteListUpgradeableProxy.sol

Listing 3.7: ZKTVestingUpgradeableProxy.sol

Listing 3.8: ZKTDepositUpgradeableProxy.sol

We understand the need of the privileged functions for contract operation, but at the same time the extra power to the <code>\_owner</code> and <code>admin</code> may also be a counter-party risk to the contract users. Therefore, we list this concern as an issue here from the audit perspective and highly recommend making these privileges explicit or raising necessary awareness among contract users.

**Recommendation** Make the list of extra privileges granted to \_owner and admin explicit to zkTube users.

**Status** The issue has been confirmed. According to the feedback from zkTube team, the roles of these two administrator can only be enabled when Ethereum itself or contracts may cause loss of users' assets due to unknown vulnerabilities.

# 4 Conclusion

In this audit, we have analyzed the ZKT design and implementation. As the value carrier of zkTube, ZKT supports staking, CPU mining and import wallet mining, and the income is ZKT. The current code base is well organized and those identified issues are promptly confirmed and resolved.

Meanwhile, we need to emphasize that Solidity-based smart contracts as a whole are still in an early, but exciting stage of development. To improve this report, we greatly appreciate any constructive feedbacks or suggestions, on our methodology, audit findings, or potential gaps in scope/coverage.
