1 Introduction

Given the opportunity to review the design document and related source code of the given contracts of 2CrazyNFT, we outline in the report our systematic approach to evaluate potential security issues in the smart contract implementation, expose possible semantic inconsistencies between smart contract code and design document, and provide additional suggestions or recommendations for improvement. Our results show that the given version of smart contracts can be further improved due to the presence of several issues related to either security or performance. This document outlines our audit results.

1.1 About 2CrazyNFT

2CrazyNFT is a revolutionary NFT trade platform, which greatly contributes to drive the NFT space to fuel mainstream adoption. In particular, 2CrazyNFT provides a robust and flexible NFT trade framework that allows third parties to integrate their own applications into it. 2CrazyNFT enriches the NFT market and also presents a unique contribution to current DeFi ecosystem.

The basic information of the audited contracts is as follows:

1.2 About PeckShield

PeckShield Inc. [11] is a leading blockchain security company with the goal of elevating the security, privacy, and usability of current blockchain ecosystems by offering top-notch, industry-leading services and products (including the service of smart contract auditing). We are reachable at Telegram (https://t.me/peckshield), Twitter (http://twitter.com/peckshield), or Email (contact@peckshield.com).

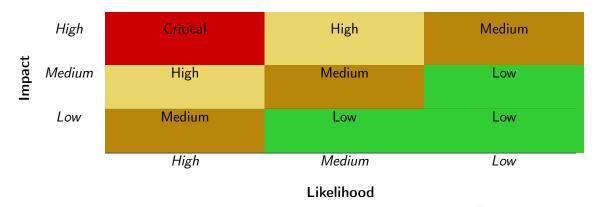

Table 1.2: Vulnerability Severity Classification

1.3 Methodology

To standardize the evaluation, we define the following terminology based on OWASP Risk Rating Methodology [10]:

- <u>Likelihood</u> represents how likely a particular vulnerability is to be uncovered and exploited in the wild;
- Impact measures the technical loss and business damage of a successful attack;
- Severity demonstrates the overall criticality of the risk.

Likelihood and impact are categorized into three ratings: *H*, *M* and *L*, i.e., *high*, *medium* and *low* respectively. Severity is determined by likelihood and impact and can be classified into four categories accordingly, i.e., *Critical*, *High*, *Medium*, *Low* shown in Table 1.2.

To evaluate the risk, we go through a list of check items and each would be labeled with a severity category. For one check item, if our tool or analysis does not identify any issue, the contract is considered safe regarding the check item. For any discovered issue, we might further

deploy contracts on our private testnet and run tests to confirm the findings. If necessary, we would additionally build a PoC to demonstrate the possibility of exploitation. The concrete list of check items is shown in Table 1.3.

In particular, we perform the audit according to the following procedure:

- Basic Coding Bugs: We first statically analyze given smart contracts with our proprietary static code analyzer for known coding bugs, and then manually verify (reject or confirm) all the issues found by our tool.
- <u>Semantic Consistency Checks</u>: We then manually check the logic of implemented smart contracts and compare with the description in the white paper.
- Advanced DeFi Scrutiny: We further review business logics, examine system operations, and place DeFi-related aspects under scrutiny to uncover possible pitfalls and/or bugs.
- Additional Recommendations: We also provide additional suggestions regarding the coding and development of smart contracts from the perspective of proven programming practices.

To better describe each issue we identified, we categorize the findings with Common Weakness Enumeration (CWE-699) [9], which is a community-developed list of software weakness types to better delineate and organize weaknesses around concepts frequently encountered in software development. Though some categories used in CWE-699 may not be relevant in smart contracts, we use the CWE categories in Table 1.4 to classify our findings.

1.4 Disclaimer

Note that this security audit is not designed to replace functional tests required before any software release, and does not give any warranties on finding all possible security issues of the given smart contract(s) or blockchain software, i.e., the evaluation result does not guarantee the nonexistence of any further findings of security issues. As one audit-based assessment cannot be considered comprehensive, we always recommend proceeding with several independent audits and a public bug bounty program to ensure the security of smart contract(s). Last but not least, this security audit should not be used as investment advice.

Table 1.4: Common Weakness Enumeration (CWE) Classifications Used in This Audit

| Category | Summary |
|----------------------------|--|
| Configuration | Weaknesses in this category are typically introduced during |
| | the configuration of the software. |
| Data Processing Issues | Weaknesses in this category are typically found in functional- |
| | ity that processes data. |
| Numeric Errors | Weaknesses in this category are related to improper calcula- |
| | tion or conversion of numbers. |
| Security Features | Weaknesses in this category are concerned with topics like |
| | authentication, access control, confidentiality, cryptography, |
| | and privilege management. (Software security is not security |
| | software.) |
| Time and State | Weaknesses in this category are related to the improper man- |
| | agement of time and state in an environment that supports |
| | simultaneous or near-simultaneous computation by multiple |
| | systems, processes, or threads. |
| Error Conditions, | Weaknesses in this category include weaknesses that occur if |
| Return Values, | a function does not generate the correct return/status code, |
| Status Codes | or if the application does not handle all possible return/status |
| | codes that could be generated by a function. |
| Resource Management | Weaknesses in this category are related to improper manage- |
| | ment of system resources. |
| Behavioral Issues | Weaknesses in this category are related to unexpected behav- |
| | iors from code that an application uses. |
| Business Logics | Weaknesses in this category identify some of the underlying |
| | problems that commonly allow attackers to manipulate the |
| | business logic of an application. Errors in business logic can |
| | be devastating to an entire application. |
| Initialization and Cleanup | Weaknesses in this category occur in behaviors that are used |
| | for initialization and breakdown. |
| Arguments and Parameters | Weaknesses in this category are related to improper use of |
| | arguments or parameters within function calls. |
| Expression Issues | Weaknesses in this category are related to incorrectly written |
| | expressions within code. |
| Coding Practices | Weaknesses in this category are related to coding practices |
| | that are deemed unsafe and increase the chances that an ex- |
| | ploitable vulnerability will be present in the application. They |
| | may not directly introduce a vulnerability, but indicate the |
| | product has not been carefully developed or maintained. |

2 | Findings

2.1 Summary

Here is a summary of our findings after analyzing the 2CrazyNFT implementation. During the first phase of our audit, we study the smart contract source code and run our in-house static code analyzer through the codebase. The purpose here is to statically identify known coding bugs, and then manually verify (reject or confirm) issues reported by our tool. We further manually review business logic, examine system operations, and place DeFi-related aspects under scrutiny to uncover possible pitfalls and/or bugs.

| Severity | # of Findings |
|---------------|---------------|
| Critical | 0 |
| High | 1 |
| Medium | 1 |
| Low | 3 |
| Informational | 0 |
| Total | 5 |

We have so far identified a list of potential issues: some of them involve subtle corner cases that might not be previously thought of, while others refer to unusual interactions among multiple contracts. For each uncovered issue, we have therefore developed test cases for reasoning, reproduction, and/or verification. After further analysis and internal discussion, we determined a few issues of varying severities that need to be brought up and paid more attention to, which are categorized in the above table. More information can be found in the next subsection, and the detailed discussions of each of them are in Section 3.

2.2 Key Findings

Overall, these smart contracts are well-designed and engineered, though the implementation can be improved by resolving the identified issues (shown in Table 2.1), including 1 high-severity vulnerability, 1 medium-severity vulnerability, and 3 low-severity vulnerabilities.

ID Title Status Severity Category **PVE-001** Potential Reentrancy Risk In TwoCrazy Low Time and State Fixed **PVE-002** Fixed High Improper Logic Of withdrawFunds() **Business Logic PVE-003** Low Accommodation Non-ERC20-**Coding Practices** Fixed Compliant Tokens PVE-004 Low Incompatibility With Deflationary/Re-Business Logic Confirmed basing Tokens **PVE-005** Medium Trust Issue Of Admin Keys Security Features Confirmed

Table 2.1: Key 2CrazyNFT Audit Findings

Beside the identified issues, we emphasize that for any user-facing applications and services, it is always important to develop necessary risk-control mechanisms and make contingency plans, which may need to be exercised before the mainnet deployment. The risk-control mechanisms should kick in at the very moment when the contracts are being deployed on mainnet. Please refer to Section 3 for details.

3 Detailed Results

3.1 Potential Reentrancy Risk In TwoCrazy

• ID: PVE-001

Severity: LowLikelihood: Low

Impact:Low

• Target: TwoCrazy

Category: Time and State [8]CWE subcategory: CWE-682 [3]

Description

A common coding best practice in Solidity is the adherence of checks-effects-interactions principle. This principle is effective in mitigating a serious attack vector known as re-entrancy. Via this particular attack vector, a malicious contract can be reentering a vulnerable contract in a nested manner. Specifically, it first calls a function in the vulnerable contract, but before the first instance of the function call is finished, second call can be arranged to re-enter the vulnerable contract by invoking functions that should only be executed once. This attack was part of several most prominent hacks in Ethereum history, including the DAO [13] exploit, and the recent Uniswap/Lendf.Me hack [12].

In the TwoCrazy contract, we notice the buyNFT() routine has the potential reentrancy risk. To elaborate, we show below the code snippet of the buyNFT() routine in the TwoCrazy contract. In the buyNFT() routine, we notice ERC20(feeToken).safeTransferFrom(msg.sender, address(this), currentNFT.price * amount) (lines 873-877) is called to transfer the feeToken to the TwoCrazy contract before purchases[msg.sender][farmIndex][NFTIndex] and farmNFTs[farmIndex][NFTIndex].totalPurchased update. If the feeToken faithfully implements the ERC777-like standard, then the buyNFT() routine is vulnerable to reentrancy and this risk needs to be properly mitigated.

Specifically, the ERC777 standard normalizes the ways to interact with a token contract while remaining backward compatible with ERC20. Among various features, it supports send/receive hooks to offer token holders more control over their tokens. Specifically, when transfer() or transferFrom () actions happen, the owner can be notified to make a judgment call so that she can control (or even reject) which token they send or receive by correspondingly registering tokensToSend() and

tokensReceived() hooks. Consequently, any transfer() or transferFrom() of ERC777-based tokens might introduce the chance for reentrancy or hook execution for unintended purposes (e.g., mining GasTokens).

In our case, the above hook can be planted in ERC20(feeToken).safeTransferFrom(msg.sender, address(this), currentNFT.price * amount) (lines 873-877) before purchases[msg.sender][farmIndex][NFTIndex] and farmNFTs[farmIndex][NFTIndex].totalPurchased update. By doing so, the limit of maxUserPurchases and currentNFT.totalSupply can be bypassed, which directly undermines the assumption of the TwoCrazy design.

```
840
         function buyNFT(uint256 farmIndex, uint256 NFTIndex, uint256 amount)
841
842

905
```

Listing 3.1: TwoCrazy::buyNFT()

Note other routines, i.e., stake() and withdraw(), can also benefit from the reentrancy protection. Additionally, we believe it's a better option for the buyNFT() and withdrawFunds() routines to follow the known best practice of the checks-effects-interactions pattern.

Recommendation Add necessary reentrancy guards to prevent unwanted reentrancy risks.

Status The issue has been addressed in this commit: fb43fbb.

3.2 Improper Logic Of withdrawFunds()

• ID: PVE-002

• Severity: High

Likelihood: Medium

• Impact: High

• Target: TwoCrazy

• Category: Business Logic [7]

• CWE subcategory: CWE-841 [4]

Description

According to the 2CrazyNFT design, the TwoCrazy contract will likely accumulate a huge amount of assets with the increased transactions through buyNFT(), while the privileged EDITOR_ROLE account has capability to withdraw the assets with the calling of withdrawFunds(). While examining the logic of the withdrawFunds() routine, we observe there is an improper implementation that needs to be improved.

To elaborate, we show below the related code snippet of the withdrawFunds() routine. In the withdrawFunds() routine, we notice ERC20(feeToken).transferFrom(address(this), msg.sender, feesCollected[feeToken]) is called to transfer the feeToken locked in address(this) to msg.sender. This is reasonable under the assumption that the transferFrom()'s implementation of feeToken supports the user spends his/her own token without approval. Otherwise, the feeToken locked in the TwoCrazy contract will be lost forever.

```
function withdrawFunds(address feeToken) public payable onlyRole(EDITOR_ROLE) {
    ERC20(feeToken).transferFrom(address(this), msg.sender, feesCollected[feeToken])
    ;
    feesCollected[feeToken] = 0;
}
```

Listing 3.2: TwoCrazy::withdrawFunds()

Recommendation Correct the implementation of the withdrawFunds() routine as below.

```
function withdrawFunds(address feeToken) public payable onlyRole(EDITOR_ROLE) {
    uint256 collectedFees = feesCollected[feeToken];
    feesCollected[feeToken] = 0;
    ERC20(feeToken).safeTransfer(msg.sender, collectedFees);
}
```

Listing 3.3: TwoCrazy::withdrawFunds()

Status The issue has been addressed in this commit: fb43fbb.

3.3 Accommodation Of Non-ERC20-Compliant Tokens

ID: PVE-003

• Severity: Low

Likelihood: Low

• Impact: Low

• Target: TwoCrazy

• Category: Coding Practices [6]

• CWE subcategory: CWE-1109 [1]

Description

Though there is a standardized ERC-20 specification, many token contracts may not strictly follow the specification or have additional functionalities beyond the specification. In this section, we examine the transfer() routine and possible idiosyncrasies from current widely-used token contracts.

In particular, we use the popular token, i.e., ZRX, as our example. We show the related code snippet below. On its entry of transfer(), there is a check, i.e., if (balances[msg.sender] >= _value && balances[_to] + _value >= balances[_to]). If the check fails, it returns false. However, the transaction still proceeds successfully without being reverted. This is not compliant with the ERC20 standard and may cause issues if not handled properly. Specifically, the ERC20 standard specifies the following: "Transfers _ value amount of tokens to address _ to, and MUST fire the Transfer event. The function SHOULD throw if the message caller's account balance does not have enough tokens to spend."

```
64
       function transfer(address _to, uint _value) returns (bool) {
65
           //Default assumes total Supply can't be over max (2^256 - 1).
66
           if (balances[msg.sender] >= _value && balances[_to] + _value >= balances[_to]) {
67
                balances[msg.sender] -= _value;
68
                balances[_to] += _value;
69
                Transfer(msg.sender, _to, _value);
70
                return true;
71
           } else { return false; }
72
73
74
       function transferFrom(address _from, address _to, uint _value) returns (bool) {
            if (balances[_from] >= _value && allowed[_from][msg.sender] >= _value &&
75
                balances[_to] + _value >= balances[_to]) {
76
                balances[_to] += _value;
                balances[_from] -= _value;
77
78
                allowed[_from][msg.sender] -= _value;
79
                Transfer(_from, _to, _value);
80
                return true;
81
           } else { return false; }
82
```

Listing 3.4: ZRX.sol

Because of that, a normal call to transfer() is suggested to use the safe version, i.e., safeTransfer (), In essence, it is a wrapper around ERC20 operations that may either throw on failure or return false without reverts. Moreover, the safe version also supports tokens that return no value (and instead revert or throw on failure). Note that non-reverting calls are assumed to be successful. Similarly, there is a safe version of transferFrom() as well, i.e., safeTransferFrom().

In the following, we show the withdraw() routine in the TwoCrazy contract. If the USDT token is supported as stakingToken, the unsafe version of require(ERC20(stakingToken).transfer(msg.sender, withdrawAmount)) (line 512) may revert as there is no return value in the USDT token contract's transfer () implementation. We may intend to replace require(ERC20(stakingToken).transfer(msg.sender, withdrawAmount)) (line 512) with ERC20(stakingToken).safeTransfer(msg.sender, withdrawAmount).

```
471
         function withdraw(uint256 farmIndex)
472
         public
473
         farmExists(farmIndex)
474
         farmValid(farmIndex)
475
476
             uint256 withdrawAmount = 0;
477
             for (
478
                 uint256 i = 0;
479
                 i < farmStakes[farmIndex][msg.sender].length;</pre>
480
481
             ) {
482
                 uint256 lockPeriod = farmStakes[farmIndex][msg.sender][i]
483
                     .lockPeriod * 86400; // days to deconds
484
                 uint256 secondsSinceCreated = block.timestamp -
485
                     farmStakes[farmIndex][msg.sender][i].createdAt;
486
487
                 if (
488
                     secondsSinceCreated >= lockPeriod &&
489
                      !farmStakes[farmIndex][msg.sender][i].withdrew
490
                 ) {
491
                     withdrawAmount =
492
                          withdrawAmount +
493
                          farmStakes[farmIndex][msg.sender][i].amount;
494
495
                     farmStakes[farmIndex][msg.sender][i].withdrew = true;
496
                 }
             }
497
498
499
             require(withdrawAmount > 0, "user have no tokens to withdraw");
500
501
             farms[farmIndex].totalStaked =
502
                 farms [farmIndex].totalStaked -
503
                 withdrawAmount;
504
505
             farmBalances[farmIndex][msg.sender].amount =
506
                 farmBalances[farmIndex][msg.sender].amount -
507
                 withdrawAmount;
508
```

```
userStakes[msg.sender] = userStakes[msg.sender] - withdrawAmount;

// transfer back the user his stakes
require(ERC20(stakingToken).transfer(msg.sender, withdrawAmount));

emit Withdrew(msg.sender, farmIndex, withdrawAmount);
}
```

Listing 3.5: TwoCrazy::withdraw()

Note other routines, i.e., stake() and withdrawFunds(), can be similarly improved.

Recommendation Accommodate the above-mentioned idiosyncrasy with safe-version implementation of ERC20-related transfer() and transferFrom().

Status The issue has been addressed in this commit: fb43fbb.

3.4 Incompatibility With Deflationary/Rebasing Tokens

• ID: PVE-004

• Severity: Low

Likelihood: Low

• Impact: Low

• Target: TwoCrazy

• Category: Business Logic [7]

• CWE subcategory: CWE-841 [4]

Description

By design, the TwoCrazy contract is the main entry for interaction with users. In particular, one entry routine, i.e., stake(), accepts user deposits of the supported stakingToken assets. Naturally, the contract implements a number of low-level helper routines to transfer assets in or out of the TwoCrazy contract. These asset-transferring routines will work well under the assumption that the vault's internal asset balances (specified by the farmBalances[farmIndex][msg.sender].amount) are always consistent with actual token balances maintained in individual ERC20 token contracts.

```
415
        function stake(uint256 farmIndex, uint256 amount)
416
        external
417
        farmExists(farmIndex)
418
        farmValid(farmIndex)
419
420
             require(block.timestamp >= farms[farmIndex].startTime, "staking hasn't started
                 yet");
421
             require(block.timestamp <= farms[farmIndex].endTime, "staking has finished");</pre>
422
             require(amount > 0, "staking amount must be greater than 0");
423
             if (farms[farmIndex].lottery) {
424
                 require(!farmBalances[farmIndex][msg.sender].exists, "account can only stake
                      once on lottery");
```

```
425
                 require(farms[farmIndex].stakeAmount == amount, "lottery farm has a fixed
                     stake amount");
426
             }
427
             if (farms[farmIndex].maxUsers > 0) {
428
                 require(farms[farmIndex].maxUsers > farmAddresses[farmIndex].length, "max
                     users reached");
429
             }
430
             // transfers the amount from the sender to the contract
431
             require(
432
                 ERC20(stakingToken).transferFrom(msg.sender, address(this), amount)
433
             // farm stakes
434
435
             farmStakes[farmIndex][msg.sender].push(
436
                 Stake(
                     amount, // amount
437
438
                     block.timestamp, // createdAt
439
                     farms[farmIndex].lockPeriod, // lockPeriod from reward
440
                     false // withdrew
                 )
441
442
             );
443
             // farm user balances
444
             farmBalances[farmIndex][msg.sender].amount =
445
                 farmBalances[farmIndex][msg.sender].amount +
446
                 amount:
448
             userStakes[msg.sender] = userStakes[msg.sender] + amount;
449
             // updates total staked
450
             farms[farmIndex].totalStaked =
451
                 farms[farmIndex].totalStaked +
452
                 amount;
454
             if (!farmBalances[farmIndex][msg.sender].exists) {
455
                 farmBalances[farmIndex][msg.sender].exists = true;
456
                 farmAddresses[farmIndex].push(msg.sender);
457
             }
460
             emit Staked(
461
                 msg.sender,
462
                 farmIndex,
463
                 farms [farmIndex].lockPeriod,
464
                 amount
465
             );
466
```

Listing 3.6: TwoCrazy::stake()

However, there exist other ERC20 tokens that may make certain customizations to their ERC20 contracts. One type of these tokens is deflationary tokens that charge certain fee for every transfer () or transferFrom(). (Another type is rebasing tokens such as YAM.) As a result, this may not meet the assumption behind these low-level asset-transferring routines. In other words, the above

operations, such as stake()/withdraw(), may introduce unexpected balance inconsistencies when comparing internal asset records with external ERC20 token contracts. Apparently, these balance inconsistencies are damaging to accurate and precise portfolio management of TwoCrazy and affects protocol-wide operation and maintenance.

One possible mitigation is to measure the asset change right before and after the asset-transferring routines. In other words, instead of bluntly assuming the amount parameter in transfer() or transferFrom() will always result in full transfer, we need to ensure the increased or decreased amount in the TwoCrazy before and after the transfer() or transferFrom() is expected and aligned well with our operation. Though these additional checks cost additional gas usage, we consider they are necessary to deal with deflationary tokens or other customized ones if their support is deemed necessary.

Another mitigation is to regulate the set of ERC20 tokens that are permitted into TwoCrazy. In TwoCrazy, it is indeed possible to effectively regulate the set of tokens that can be supported. Keep in mind that there exist certain assets (e.g., USDT) that may have control switches that can be dynamically exercised to suddenly become one.

Recommendation If current codebase needs to support possible deflationary tokens, it is better to check the balance before and after the transfer()/transferFrom() call to ensure the book-keeping amount is accurate. This support may bring additional gas cost. Also, keep in mind that certain tokens may not be deflationary for the time being. However, they could have a control switch that can be exercised to turn them into deflationary tokens. One example is the widely-adopted USDT.

Status The issue has been confirmed by the team. There is no need to support deflationary/rebasing tokens.

3.5 Trust Issue Of Admin Keys

• ID: PVE-005

• Severity: Medium

Likelihood: Medium

• Impact: Medium

Description

Target: TwoCrazy

• Category: Security Features [5]

• CWE subcategory: CWE-287 [2]

In the 2CrazyNFT protocol, there is a privileged account that plays a critical role in governing and regulating the protocol-wide operations (e.g., configuring various system parameters). In the following, we show the representative functions potentially affected by the privilege of the account.

```
function toggleFarmValidity(uint256 farmIndex)

external

farmExists(farmIndex)
```

```
336
             onlyRole(EDITOR_ROLE)
337
         {
338
             farms[farmIndex].valid = !farms[farmIndex].valid;
339
             emit FarmValidityChanged(farmIndex, farms[farmIndex].valid);
340
341
342
343
344
         function toggleNFTValidity(uint256 farmIndex, uint256 NFTIndex)
345
346
             farmExists(farmIndex)
347
             onlyRole(EDITOR_ROLE)
348
349
             farmNFTs[farmIndex][NFTIndex].valid = !farmNFTs[farmIndex][NFTIndex].valid;
350
             emit NFTValidityChanged(farmIndex, NFTIndex, farmNFTs[farmIndex][NFTIndex].valid
                 );
351
        }
352
353
354
355
         function setNFTContractAddress(
356
             uint256 farmIndex,
357
             uint256 NFTIndex,
358
             address contractAddress
359
        ) external
360
        farmExists(farmIndex)
361
         onlyRole(EDITOR_ROLE) {
362
             farmNFTs[farmIndex][NFTIndex].contractAddress = contractAddress;
363
             emit NFTContractAddressChanged(farmIndex, NFTIndex, contractAddress);
364
```

Listing 3.7: TwoCrazy::toggleFarmValidity()&&toggleNFTValidity()&&setNFTContractAddress()

We emphasize that the privilege assignment may be necessary and consistent with the protocol design. However, it is worrisome if the privileged account is not governed by a DAO-like structure. Note that a compromised privileged account would allow the attacker to modify a number of sensitive system parameters, which directly undermines the assumption of the 2CrazyNFT design.

Recommendation Promptly transfer the privileged account to the intended DAO-like governance contract. All changed to privileged operations may need to be mediated with necessary timelocks. Eventually, activate the normal on-chain community-based governance life-cycle and ensure the intended trustless nature and high-quality distributed governance.

Status This issue has been confirmed by the team.

4 Conclusion

In this audit, we have analyzed the <code>2CrazyNFT</code> design and implementation. As a revolutionary <code>NFT</code> trade platform, <code>2CrazyNFT</code> is significantly contributing to drive the <code>NFT</code> space to fuel mainstream adoption. In particular, <code>2CrazyNFT</code> provides a robust and flexible <code>NFT</code> trade framework that allows third parties to integrate their own applications into it, which presents a unique contribution to current <code>DeFi</code> ecosystem. The current code base is well organized and those identified issues are promptly confirmed and fixed.

Meanwhile, we need to emphasize that smart contracts as a whole are still in an early, but exciting stage of development. To improve this report, we greatly appreciate any constructive feedbacks or suggestions, on our methodology, audit findings, or potential gaps in scope/coverage.
